# **Traffic Analysis Of McDonalds' Impact on the Intersection of Rockdale Avenue and Dartmouth Street**

**By  
Walter Freeman Associates**

## ***PROJECT DESCRIPTION***

A 5,000 square foot McDonald's Restaurant with a drive-thru service is proposed for the northwest corner of the Rockdale Avenue/Dartmouth Street intersection. There will be two drives on Rockdale Avenue on either side of the New Bedford Institution For Savings. North of the bank the drive will be one way in and south of the bank the drive will be one way out. There will be two one-way drives on Dartmouth Street. The exiting drive on Dartmouth Street will serve most of the exiting drive-thru service traffic. The Site surrounds an existing gas station at the corner. There will be a total of 68 parking spaces provided. This restaurant will replace an existing McDonald's Restaurant less than one half mile west of the site on Dartmouth Street.

## ***EXISTING CONDITIONS***

### **LANE USE, GEOMETRICS, AND LAND USE**

Figure 1 shows the existing lane width and use at the intersection of Dartmouth Street and Rockdale Avenue. Rockdale Avenue runs north/south with its southbound approach having a 10.5 foot wide through and left turn lane and an 10.5 foot wide right turn lane. The total pavement width north of Dartmouth Street is 42 feet. The northbound approach has a 12 foot wide left turn lane and a 12 foot wide through and right turn lane. The total pavement width south of Dartmouth Street is 48 feet wide. Buses stop on either side of Rockdale Avenue north of Dartmouth Street, but cause very little traffic disruption. The east side of Rockdale Avenue has a 12 foot bus stop lane while the west side has none. The southbound buses stop approximately 180 feet from the intersection.

Dartmouth Street runs east/west with its eastbound approach 20 feet wide. Vehicles on this approach frequently form two lanes. The total width west of Rockdale Avenue is 38.5 feet. The westbound approach has an 18.5 foot wide left and through lane and a 12.5 foot wide right turn lane. The total pavement width east of Rockdale Avenue is 51 feet. There is a 12 foot parking aisle approximately 80 feet from the intersection on the westbound side.

A gas station occupies the northwest corner of the intersection. On the southwest corner there is another gas station and a convenient store adjacent to a "rent to own" video equipment store. The northeast corner is an empty lot. The southeast corner is occupied by an auto service facility with a used car lot. The immediate area on Rockdale Avenue south of the intersection is light commercial and/or small business. Traffic was observed to be moderate to heavy during the weekday peak hour period and traffic entering and leaving developments near the intersection did not significantly impede traffic flow.

### **TRAFFIC SIGNAL OPERATIONS**

The intersection is controlled by a traffic signal having two vehicular phases with 26 seconds of green each within a 60 second cycle. While there are two pedestrian push button posts at the intersection, no pedestrian phases were called during our period of observation. Pedestrian activity was negligible.

### **TRAFFIC VOLUMES**

Walter Freeman Associates staff video recorded, counted, and classified the existing traffic at the intersection on Friday, November 10, 1989 during the 4:00-6:00 PM weekday peak period. Traffic counts were summarized to determine the peak hour, peak 15 minutes within the peak hour, and the percentage of heavy vehicles. Lane use and widths, signal phasing and timing were also recorded. Figure 1 shows the 1989 peak hour traffic volumes and average weekday traffic (AWDT) at the intersection.

The peak hour from 4 to 6 PM was from 4:15 to 5:15 PM, with the peak 15 minute demand occurring from 4:45 to 5:00 PM. The peak hour on this particular Friday was 13 percent higher than the average of all counted weekday peak hours.

The traffic demand on Rockdale Avenue on this Friday was actually higher from 3 to 4 PM than from 4:15 to 5:15 PM - a situation not true during other weekdays. As a consequence of this higher early demand which exceeded the capacity of both the northbound and southbound approaches, long 20 vehicle queues southbound and northbound on Rockdale Avenue existed when we began our counts. These long queues slowly declined to predicted lengths of 7.5 to 8.5 vehicles at start of green by 4:30 PM.

In the eastbound direction the average queue length was slightly more than six vehicles at start of green, while in the westbound direction start of green queues were 5 vehicles in the left/through lane and one in the right turn lane.

The traffic was recorded from November 8-14, 1989, on Rockdale Avenue north of the intersection and on Dartmouth Street west of the intersection. The counts are shown plotted on Figures 2 and 3. The average weekday traffic for northbound vehicles on Rockdale Avenue is 8,031 while the southbound average weekday traffic is 8,331 vehicles. The average weekday traffic for eastbound vehicles on Dartmouth Street is 6,279 while the westbound traffic is 5,833 vehicles.

### **TRAFFIC GENERATED BY McDONALDS**

There are two empirical studies of traffic generated by fast food restaurants with drive-through windows which we have used as references in this report plus 4:30 to 5:30 PM counts of the existing McDonald's on Dartmouth Street. One study by the Institute of Transportation Engineers (ITE) of over 30 such restaurants nationwide, including several McDonald's restaurants, is reported in Trip Generation, published in September 1987. Another study by Barton Aschman Associates of several McDonald's restaurants in the Chicago area was published in 1980.

Peak hour traffic generation rates cited by the ITE Study are generally lower than those cited by the McDonald's Study. Table 1 compares the traffic volumes predicted by each one of these studies for 5000 square foot restaurants as is proposed northwest of the intersection of Dartmouth Street and Rockdale Avenue. From 4:30 to 5:30 PM on Friday, November 10, 1989, we counted 200 vehicles entering and leaving the existing McDonald's restaurant on Dartmouth Street - 100

entered and 100 left the site. This count aged closely with the McDonald's study which predicts an average hourly volume of 202 vehicles entering and leaving McDonald's sites during the 4 to 6 PM weekday period.

For the purposes of our study we have analyzed two time periods:

1) The 12 noon to 1 PM Saturday peak hour, which generally has the greatest hourly site traffic (427), to estimate delays and queues likely to be experienced by traffic entering and leaving the site.

2) The 4 to 6 PM Friday peak hour, which generally has the greatest traffic on adjacent streets, to estimate the impact of the relocated facility on traffic operations at the intersection of Rockdale Avenue and Dartmouth Street. During this period, McDonald's typically has higher site traffic from 5 to 6 PM, but to be conservative, we have assumed that this is the highest estimated site traffic, 235 vehicles per hour, would occur during the peak hour of the intersection which is 4:15 to 5:15 PM.

Of the traffic entering the existing McDonalds site, 85 percent came from the east on Dartmouth Street and, therefore, passed through the intersection of Dartmouth Street and Rockdale Avenue. Of the traffic leaving the site, 66 percent went to the east on Dartmouth Street and, therefore, also passed through the intersection.

*There is an intersection Avoidable Shunt Street that passes from Rockdale to Dartmouth. Approx 1000' west of intersect.*  
Since the proposed restaurant will be a relocation rather than a facility completely new to the area, the traffic impact will be primarily to increase traffic entering and leaving driveways at the new location and to alter intersection turning movements at Rockdale Avenue and Dartmouth Street.

## CAPACITY AND LEVEL OF SERVICE ANALYSIS

### CAPACITY AND LEVEL OF SERVICE CRITERIA

The capacity of a signalized intersection is the maximum rate at which vehicles can normally pass through the intersection under prevailing roadway, vehicle mix, and traffic control conditions. According to the *1985 Highway Capacity Manual*, the level of service of a signalized intersection or any of its lane groups is related to the average stopped delay per vehicle. The table below gives the ranges of average stopped delay per vehicle associated with each level of service.

Level of Service	Average Stopped Delay Per Vehicle (Seconds)
A	0 to 5
B	5 to 15
C	15 to 25
D	25 to 40
E	40 to 60
F	Over 60

**Notes:**

n/a means not available.

ITE sample, while including McDonald's, explicitly states that the restaurants studied had limited or no sit-down facilities.

The McDonald's Study includes several sites in the Chicago area and was copywritten in 1980. The study was conducted by Barton-Aschman Associates, Inc., of Evanston, Illinois.

## **EXISTING CONDITIONS**

The long southbound Rockdale Avenue queue of vehicles waiting to go straight or turn left at Dartmouth Street during the PM peak will frequently extend back to and partially block the site driveway south of the New Bedford Institution for Saving. Occasionally this queue will also extend beyond both drives on Rockdale Avenue. Because of this blockage, most traffic entering the site during the peak hour from south on Rockdale Avenue and from the east on Dartmouth Street are likely to use the Dartmouth Street driveway. For the same reason, traffic leaving the site to go south on Rockdale Avenue or east on Dartmouth Street are likely to use the Dartmouth Street exit.

Traffic entering the site from the north on Rockdale Avenue will naturally use the Rockdale Avenue driveway adjacent to the bank. However, when these drivers go back north on Rockdale Avenue, those who used the drive-through window are likely to leave by the Dartmouth Street exit and turn left at the signal onto Rockdale Avenue.

Figure 4 shows our estimated weekday 4 to 6 PM peak hour and Saturday noon to 1 PM traffic entering and leaving the site if McDonald's is relocated to the proposed site.

The Rockdale Avenue/Dartmouth Street intersection traffic now experiences an average delay of over 30 seconds and a D Level of Service (LOS). The SB Rockdale Avenue critical left and through lane is oversaturated in the peak 15 minutes and its traffic has average delays of over a minute - a LOS F. The NB Rockdale Avenue approach left turn lane has delays of nearly 40 seconds with LOS D. The EB Dartmouth Street approach experiences a delay of 11 seconds and a B LOS. The left and through movements WB on Dartmouth Street have delays of 10 seconds with LOS C.

## **BUILD CONDITIONS**

With the addition of McDonald's Restaurant there will be little net change in traffic using the intersection. However some critical movements will change during the peak hour:

- southbound Rockdale Avenue through traffic will increase,
- southbound Rockdale Avenue right turning traffic will decrease, and
- eastbound Dartmouth Street left and right turning traffic will decrease.

Figure 5 shows our projected traffic volumes at the intersection of Rockdale Avenue and Dartmouth Street after the relocation of McDonalds.

These small changes in traffic volumes due to McDonald's relocation will increase delays on the southbound Rockdale Avenue approach by ten seconds at the most, will reduce the delays eastbound on Dartmouth Street, but will not change levels of service in the intersection or on any of its approaches. Average overall delays in the intersection will increase from 30.6 to 33.5 seconds per vehicle.

The most used site driveways will be those on Dartmouth Street. The busiest period for the site is expected to be from noon to one PM on Saturday. During this period delays to vehicles turning left into the site from Dartmouth Street will be approximately 5 seconds per vehicle. Delays to vehicles turning right from the site onto Dartmouth Street will also be slight - averaging less than 5 seconds per

vehicle. For vehicles leaving the site to go east on Dartmouth Street delays will vary from 15 seconds per vehicle to 19 seconds per vehicle, depending on how many use the site exit next to New Bedford Institution for Savings.

The average number of vehicles waiting to leave the site during the peak period from the Dartmouth Street driveway will be less than one.

#### **POSSIBLE TRAFFIC MITIGATIONS**

Improved Timing Existing timing at Rockdale Avenue and Dartmouth Street could be improved to reduce peak hour delays and queues. Changing the signal timing at the intersection by giving Rockdale Avenue more green time would both improve intersection capacity and Level of Service.

Holding the signal cycle length at 60 seconds, Phase 1 (N/S Rockdale Avenue) green time should be retimed to 34 seconds and Phase 2 (E/W Dartmouth Street) green time retimed to 20 seconds. Under these conditions, the average delay for the intersection would be reduced by 20 seconds per vehicle and the intersection would operate at a B Level of Service. This would be a significant improvement over the existing D Level of Service conditions.

The SB Rockdale Avenue approach delays would decrease from 77 seconds to 16 seconds and the NB Rockdale Avenue approach delays would decrease from 18 seconds to 9 seconds. The EB Dartmouth Street delay would increase from 11 seconds to 15 seconds and the WB Dartmouth Street approach delays would increase from 10 seconds to 14 seconds, but overall operations would be better.

During the peak hour with this changed signal timing, the Rockdale Avenue southbound maximum queue lengths adjacent to the site would be reduced from 7.8 vehicles to 6.5 vehicles, while the eastbound queue length on Dartmouth Street would increase slightly from 6.8 vehicles to 7.2 vehicles.

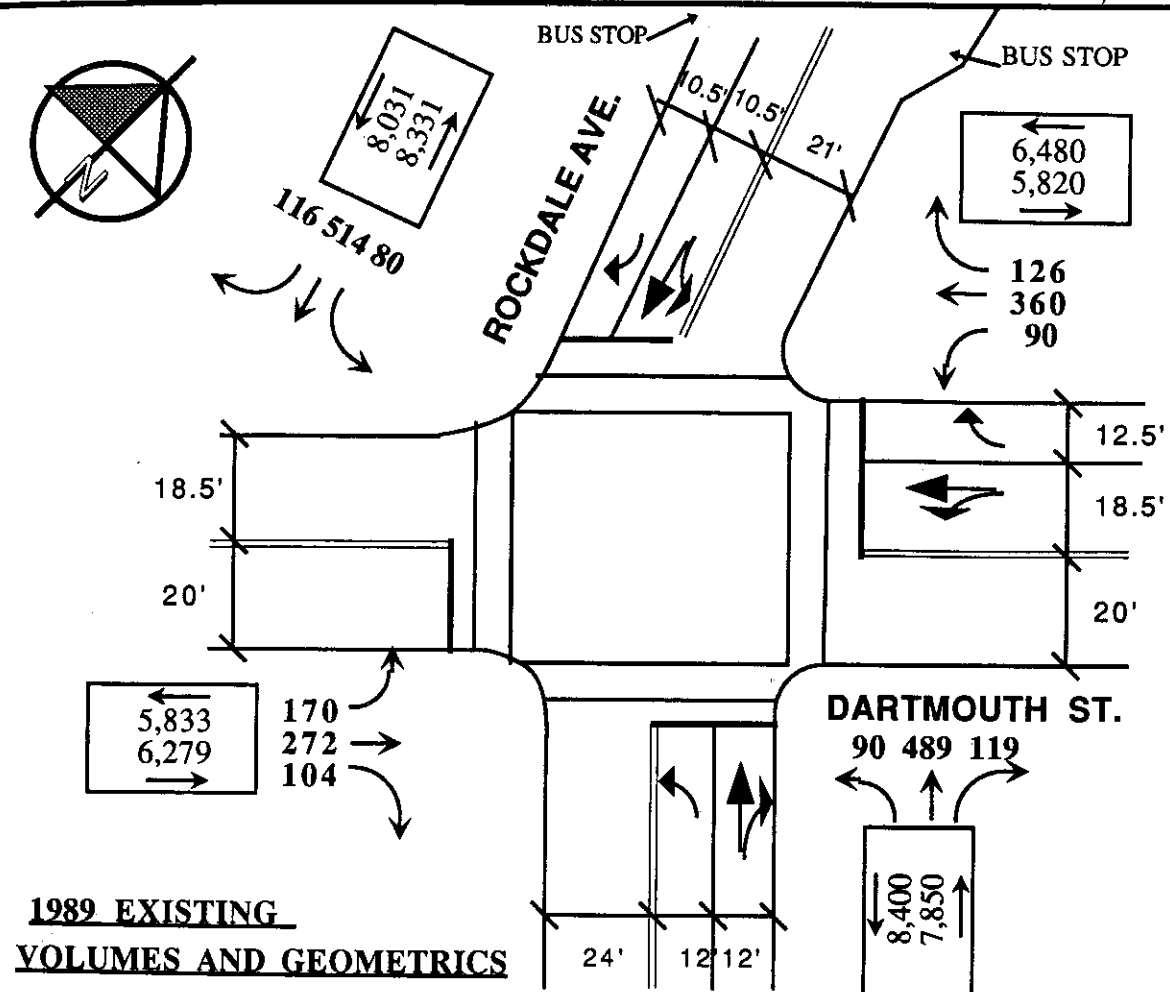

Revised Lane Use Changing the lane use and signal timing to that shown on Figure 6 would further reduce queuing on Rockdale Avenue southbound to 6.1 vehicles and reduce queuing on Dartmouth Street eastbound to 2.1 vehicles in the left turn lane and 4.9 in the curb lane.
